Abstract

Studies evaluating scientific supervision at the undergraduate level are few and heterogeneous. The aim of the study was to further explore undergraduate students’ experiences of and thoughts about research supervision.

Methods: The sample of informants consisted of 13 physical therapy students from two Swedish universities. Data collection was done using semi-structured interviews covering the areas of supervision and collaboration. Data analysis was performed according to qualitative content analysis.

Results: Three they emerged from the interviews- the role of the supervisor, the student’s perception of uncertainty and structure of the supervision

Conclusion: Physical therapy students’ experience of their supervision was dependent on the supervisors’ attributes, both favourable and unfavourable, difficulties with communication, being disregarded and affected by the supervisors’ personal views. This was also put in the context of the current form of supervision, as individual and group supervision brought both positive and negative factors to the experience of the process.

Background:

Scientific supervision as performed during bachelor courses is a regular role for lecturers at higher education institutions. The main aim of the thesis at the undergraduate level is to give students basic knowledge about the research process [1,2]. Scientific supervision differs from other forms of teaching and learning in higher education in its peculiarly intense and negotiated character, as well as in its requirements for a blend of pedagogical and personal relationship skills. Therefore, it is demanding primarily due to that the students have the lowest degree of autonomy and knowledge of scientific methodology [3]. Formative feedback has been defined as information communicated to the learner that is intended to modify the student’s thinking to improve learning [4] and should be open minded in terms as none evaluative, supportive, timely and specific. However, there are large variations both in the amount of time that is devoted to supervision and the supervisors’ approach, which can vary between focusing on the process or the product, in this case a thesis. The degrees of affiliation and control have been found to be related to outcomes of students writing their master thesis [5].

Fundamentally though, students are expected to produce a thesis but they do not have the knowledge of how to do so [6]. They also dedicate different amounts of time to the task and are more or less independent, confident and interested in the topic [7]. The students’ sex, age, family status, social background and previous studies contribute as factors in the collaboration between student and supervisor [8].

Supervision can be performed individually by one or several supervisor (-s) or in a group setting. More than one supervisor can be helpful for the student to gain a broader perspective on their work, various types of supervision approaches and, hopefully, make it easier to get the guidance they need [7]. But several supervisors can also contribute to distress as they are not always of the same opinion, which may result in dilemmas where the student does not know how to proceed [7]. The aim of group supervision is to increase the involvement of the students by reading and commenting on each other’s work throughout the writing process [9].
The supervisor’s role then changes from a relationship between two or three individuals, to between the supervisor and the group [9]. However, the students may choose to focus on an area in which the supervisor does not have the best knowledge and so their ability to help will be compromised as regards the subject matter and becomes more about project management [9]. Also the student role changes with group instruction, as participation requires preparation and contribution to the group’s meetings [9]. The different types of supervision provide different opportunities for cooperation, which affects students’ work.

Studies evaluating scientific supervision at the undergraduate level are few and heterogeneous. Two studies have evaluated it from the supervisor’s perspective. In a study by Holmberg on the perspective of the learning process in business administration, they discovered that the supervisors experienced difficulty in balancing science and practice. In a Finnish study evaluating perceptions of group supervision at a healthcare institution the lecturers perceived their role as experts and coaches of teams of students who would work together [10,11]. But they also expressed that it was a problem to get enough time for supervision in different phases of the work i.e. ‘mismatch’ between the needs and time for supervising.

There are a few studies exploring the students’ perspective. In teacher education, students found practical-oriented supervision preferable to create a good learning process when compared to traditional supervision, which was perceived as solely focusing on the final product, the thesis [1]. The Finnish study described earlier correspondingly assessed students’ perceptions [10,11]. The result describes positive student experiences of group supervision due to the dynamic ways in which learning activities could take place and students could be involved in each other’s processes. However, if the students only focused on their own work it was a risk that they would perceive the group supervision as meaningless. Group supervision from the students’ perspective has also been studied in a group of Japanese students in a thesis course in the humanities [12]. The results emerged that the students felt that the seminars allowed them to gain knowledge from their classmates and it was good to receive feedback from more than just the supervisor. The students also experienced that the group supervision better socialized them into academic writing. In an English study of students in a social work programme, the students were supervised in groups or individually [13]. At the midpoint of the study, the students who were being supervised as a group had significantly higher hope of learning more about the topic and developing their writing skills compared to the students who were being supervised individually. Individual supervision has also been studied in students studying economics at a South African college [14] where the students expressed the opinion that they received too little supervision to be able to write an academic thesis. The students understood what was missing but they did not know how to change the text to meet the expectations.

Hence, the rational for this study is a lack of research focusing on bachelor thesis courses, with only a few articles investigating the scientific supervision on this level. Implications for further investigating the students’ experiences of bachelor thesis supervision has also been addressed in order to develop learning and teaching activities during this initial encounter of the students in producing research [15,16]. To our knowledge, no previous research has investigated the type of scientific supervision in physiotherapy programs. Based on this knowledge, the aim of this study was to explore undergraduate students’ experiences and thoughts about scientific supervision.

**Methods**

The study was conducted by a qualitative, inductive approach with semi-structured individual interviews and analysed using context analysis as described.

**Informants and context of the study**

Based on the rational for this study, a focus on bachelor thesis course in physiotherapy was chosen. In Sweden, a total of eight universities and university collages provide this program. Applications to the program are made through a national web-site and no study-fees are charged from the students from the European Union. The programme is given as full-time during three years and result in both a diploma as Physiotherapist and a Bachelor of Science in Medicine with a focus on Physiotherapy. The bachelor course is given during the third year and supervisors are lecturers or clinical lectures with a master or doctoral degree.

In this study, a convenient sample was used based on students from the University of Gothenburg (Gothenburg) and the Karolinska Institute (Stockholm). In Gothenburg the course that includes the bachelor’s thesis initiates during the fifth semester when students decide the topic and write a research plan with assistance from the supervisor. The work for the thesis is then carried out during the sixth semester. According to the syllabus, five occasions of supervision is included. However, the actual supervision time that each student receives varies. The course ends with a viva voce examination where the thesis is presented and discussed.

During the autumn semester of 2013, group supervision was initiated. Supervision groups were put together consisting of four project groups with two students in each group. Each group was supervised by two lecturers, as the model for group supervision was new. Meetings were scheduled with themes such as ‘Background, aim and hypotheses’, ‘Method’ and ‘Results’. During the semester the majority of the students had group supervision, though some
still had individual supervision.

The Physical Therapy program at Karolinska Institute in Stockholm has the same construction of the bachelor’s thesis course as the University of Gothenburg, but with a tradition of performing group supervision with students in the Physical therapy programme.

Students within the last semester of the programme were approached. Invitation to participate was performed by written and oral information about the study after the examinations in the bachelor’s thesis course.

A first sample of informants consisted of 11 students who responded positively out of 20 strategically chosen from the group in Gothenburg. Initial contacted was done via e-mail and aimed at strategically sampling for age, gender and diversity in receiving individual or group supervision. Students who were being supervised by the authors were excluded from the study. To avoid having a sample that only represented students from one university; a group of students from the physical therapy programme at the Karolinska Institute, Stockholm were also included. When two additional interviews were carried out and nothing new had emerged, data collection was stopped. The students who participated were between 20 and 40 years of age, nine were women and four men, four had received individual supervision and nine group supervision.

Data collection

The interviews were conducted individually at the university hospital or university. The last interviews were conducted by telephone due to logistic reasons. The data collection was made using semi-structured interviews. The interviews covered the following areas:

- Examples of good / less good supervision in the different phases of the thesis work
- Description of optimal supervision.
- The collaboration between the student and the supervisor

Follow-up questions such as the following were used to engage the student more deeply.

The interviews were recorded with standard cassette tapes and with a voice recorder. The interviews were transcribed verbatim.

Data analysis

Content analysis is a method of analysing written, verbal or visual communication messages and a research method which is a systematic and objective means of describing and quantifying phenomena [17].

The analysis was performed by the two authors, independently of one another according to the following steps described.

1. The text was read through several times to create a sense of wholeness.
2. Areas included in the aim were marked in the text – units of analysis
3. The marked areas were divided into meaning units.
4. The meaning units were condensed, ie, the sentences were shortened without changing the meaning.
5. The condensed text was abstracted which means that the content and interpretation of the condensed text was described at a higher logical level in a code.
6. These codes were then sorted based on similarities and differences. The codes were divided into themes and sub-categories.

The analysis and coding were discussed until a consensus arose.

Ethics

This study was conducted as a part of a thesis project in pedagogics. The ethics were reviewed, monitored and approved by the University of Gothenburg in accordance with Swedish law on ethics in research (Prop.2007/08:44; Law 2003:460). Permission to carry out the study was given by the respective head of the physical therapy programmes. All participation was voluntary, and all data were collected anonymously. The informants participated after verbal and written information was provided and their written consent, except in cases where the interviews were conducted by telephone, where the approval was given orally.

Internal ethics guidelines for the transcription of the interviews were followed as to how pauses, repetitions, etc. would be handled. The two authors did the analysis separately to increase credibility and to reduce the risk that the information would be distorted or taken out of context.

Results

Analysis of the 13 interview resulted in three themes: ‘The role of the supervisor’, ‘Perception of uncertainty’ and ‘Structure of the supervision’. These were divided into categories and sub-categories as illustrated in Table.
The role of the supervisor

The informants describe cooperation with the supervisor as very important. Cooperation was perceived as vital in all steps of the research process; planning, data collection, analysis and writing the thesis. Both good and bad experiences and attributes throughout this process were described. There were two categories in the theme, the superior and the inferior supervisor.

The superior supervisor

Experiences of positive qualities that were desirable in a supervisor were described by the informants based on their own experiences but also reflection after hearing about experiences of other students in the class.

Above all the informants said it was important that the supervisor is competent in the research design of the project. In cases where students had a quantitative approach, several students mentioned that it was necessary that the supervisor was qualified in statistics. They wanted the supervisor to be competent in the topic of the study, but this was secondary to knowledge of research design.

‘The supervisor must of course have knowledge about the topic you choose to write about. Some knowledge of what my work is about and also, of course, an understanding of statistics, because that was what we had a lot of questions about.’

A fundamental element was that the supervisor had time and was available. The participants described that it was important that there be enough time for discussion during the planned meetings. But that it was also important that the supervisor be available for contact via email or phone outside the pre-arranged meeting times.

‘I think it is most important that you have time to supervise. That the supervisor has time’

The informants wanted a supervisor who was straightforward, clear, committed and was interested in the students’ work and respectful of the students’ opinions. They should also have a positive attitude and a willingness to guide students through the work with their thesis.

‘That they primarily are interested. But also that they have to have the ability to know how the work should be written and structured ... to be respectful towards those who write’

The inferior supervisor

All the informants had experienced more or less good supervision. But they described inferior supervisors as those who were uncommitted to the students and their writing, to the topic or someone who does not devote enough time to supervision or had a negative attitude towards supervision generally.

‘Having little personal involvement, little interest in the subject area and not really having time for your students. . . . I don’t know how you get to be a supervisor, but I think that if you are, you should have time for your student and the ability to devote time to them. You can’t say “maybe I can reply [to your email] next week.’. In that case, you shouldn’t be a supervisor.’

Another aspect was that the supervisor should not be too strict and controlling which seemed to be a risk if they had a lot of expertise in the topic. The supervisor might not allow for the students to develop the process and influence the work as much as they would like. Instead controlling everything based on his/her own knowledge and understanding.

‘It is possible that the supervisor takes a lot of control… if the supervisor is very good with methodology and very good in the area, it is possible that the supervisor takes over a little bit, provides a little too much input and the students then may not have the space to be creative and learn. But this is still a learning experience.’

The informants’ perception of uncertainty

Several experiences were described by the informants, when confusion had prevailed, leading to uncertainty which sometimes delayed the work process. The category includes both the frustration in the cooperation and the ambiguity in instructions and information given.

The informants’ experiences of frustration

Several participants shared that they had experienced difficulties in communicating with the supervisor and other lecturers included in the course which lead to frustration and uncertainty. The time schedule was so tight that minor lapses in communication lead to delays in the work. ‘It was when we were doing statistics. X (one of the lecturers) didn’t have time for us right then. And we understood that, but then we tried to email Y (another lecturer)
but we did not get any response. We thought that was a bit frustrat-
ing because we did not know if it was because [she knew] we had
another supervisor or if she just didn’t have time. ‘Disregard was
experienced and expressed by some participants. They described
situations where they felt that the work was unimportant or did
not mean anything to the supervisor. Some experienced concerns
that the supervisor forgot what had been decided and this delayed
the process. One fear was that the supervisor actually had poor
control and approved everything without requiring further work
from the students, meaning important aspects may be overlooked.
‘It was noticeable especially during the examination where we
found that the examiner brought up the things that we absolutely
ought to have already heard about during the time we were being
supervised. We had been a little too focused on our own work and
had not thought of those things. But it was very obvious when we
heard it [from the examiner/s].

We felt that supervisors should have commented on it more
[during supervision]. ‘The informants’ perception of ambiguity the
informants described that the written and oral instructions they re-
ceive before and during the course was often unsatisfactory. This
lead to uncertainty in their work, difficulties to know the frames
and different interpretations increasing their work load. Especially
at the start of the work it was important to get specific and cor-
correct information in order to eliminate delays. ’The attitudes of
the lecturers were very much focused on not being worried, and
that things would “be resolved”. We wanted to know when we
had to do the different tasks. It was very unclear. It was frustrat-
ing with the “it will be resolved” mentality. We were not at all on
board with it. ‘A common experience was that some supervisors
approved what other supervisors did not. It included both formal-
ities and the structure of the project and thesis. This lead to a lot
of uncertainty. Some participants felt unfairly treated.’ You heard that
other people’s supervisors had been saying specifically that “you
must do this” or “this mustn’t be done” but later it was shown that
this wasn’t the case.’

Structure of the supervision

Positive and negative aspects of structure of group and indi-
vidual supervision were described by the students.

Group supervision

Seven of the eleven participants had had group supervision. Both
positive and negative experiences were expressed, though
they were predominantly negative. The advantages of group su-
pervision over individual supervision included using the peer-
reviewing process, with several people reading through written
work. Students stated that being able to express and receive ideas,
change their perspective and get feedback on their work was also
an advantage of group supervision. One of the participants, who
expressed a difficult start-up phase, described group supervision
as a positive source for ideas on how to advance and engage the
problems of research design. Other participants expressed that
their thinking about the research processes and research construc-
tion had been positively affected by the group intervention and the
diversity in aims. This knowledge was of great value during the
opposition and defense seminars.

“I believe that it worked well because I and my thesis-partner
started off a little late... I believed was very good being in a group
and hearing the others” questions and thoughts and how they were
doing their projects. So if you didn’t understand that well, you
were able to better understand [by listening to others in the group].
And that question arose in our group and they were answered very
well. I believe it helped everyone and to also be able to throw ideas
around about each other’s theses.’

‘I also had the opportunity to provide feedback. It was one
of the projects which I was very interested in I thought it was a
very good idea and something valuable to do. And then I got the
opportunity to help them. I brought up something that they were
able to use. That was fun!’

Disadvantages with group supervision was stated as lack of
or difficulties to commence good Disadvantages of group supervi-
sion were stated as lack of or difficulties starting good and con-
structive discussions in the group when the students were in dif-
fferent phases of the research process. Some students in the group
were already in the middle of the process at the start of the course,
while others did not begin until sometime later. The ones who had
already started experienced lack of supervision compared to their
current need, and that the supervision session only became for-
mal attending occasions necessary to be approved of to get course
credits. The students were mostly passive during the meetings and
not particularly interested in the others’ work. As there was a lack
of correlation between the discussions during the sessions to their
own individual projects, the students generally did not commit to
reading the project papers of other students. They experienced the
time in between supervision sessions to be a frustration, as this de-
layed the progress of their project. They suggested that individual
supervision could be used to complement group supervision ses-
sions. All the group supervision participants experienced a lack of
more individual support at one or several times during the project.

‘It started well and you were able to get going and make
progress, while at the same time others had a really hard time even
deciding what they were going to do. So there was a great deal of
focus on them and getting them started with their work. Which of
course they needed, but at the same time you felt that you were not
making progress because you weren’t getting the supervision you
wanted. I think it would be better to have had individual supervi-
sion.’
Using two supervisors was seen as hindering the learning process by students in group supervision. This led to students being unsure who to contact when they needed help as the responsibilities of each supervisor were not clear. In some cases, the supervisors were at odds with each other concerning super visional guidance, which made it hard for the students to choose whom to listen to and to trust. The participants who experienced this would have preferred to have only one supervisor or mix between group and individual supervision to minimize these problems.

**Individual supervision**

Similarly to those who had had group supervision, those who had had individual supervision also experienced positive and negative perceptions. A beneficial aspect of the learning process in individual supervision was the total and solitary focus on one’s own thesis. No consideration had to be taken to other research processes, methods or texts, just their own work and the supervisor was fully focused on the current status of the work in progress. The supervisor had, in most cases, made up a timetable for the work process and communication was continuous with contact via e-mail, telephone and SMS.

‘We could email, call and meet our supervisor pretty much whenever we wanted, and we thought that was very good. At the beginning we had a lot of questions that we needed help with so we could get started and then we were more independent the rest of the time.’

As regards negative experiences, the supervisors’ role as the only source of reflection and perspective of the work could be a vulnerability, particularly if contact and the relationship with the supervisor was compromised, leading to uncertainty of procedure and extension of the work. Assumptions among the participants with this experience expressed a belief that group supervision might have decreased the risk of such dilemmas as feedback could be given within the student group.

‘I think that it was better to have individual [supervision] but. If group supervision works really well then perhaps it is also really rewarding. Like being able to give each other a bit of feedback.’

**Discussion**

The purpose of this study was to explore how undergraduate students’ writing a bachelor’s thesis experienced scientific supervision during their physical therapy course. Earlier studies in this area are few and heterogeneous, highlighting both the students’ and the supervisors’ perspective. The study focused on the students’ perspective and a group that has not previously been investigated, physical therapy students. Previous studies in healthcare programmers have evaluated the healthcare students’ perspective [11,12] but there are still topics left to focus on.

The results of this study indicate that many of the participants were satisfied and had a positive experience of the course and the supervision, but they also described shortcomings and problems. The supervisor’s role is essential to the quality of work and the process of supervision. The participants describe that a superior supervisor must have time for guidance, knowledge of the scientific method and a positive attitude to the topic. In contrast, they felt an unengaged supervisor who controls too much, ‘takes over’ or did not have the time was less desirable. The participants described that they want a coach or consultant, which is in line with results from a previous study the participants expressed the same desire that student in a teacher program in the study by [1] who wanted a supervisor who would be involved and would guide them throughout the process. However, the participants in the current study didn’t want a ‘parent’, which some of the supervisors in study perceived they as being for their students. Based on the findings and previous research, it seems the guidance during the process is most important for bachelor level students in healthcare the first time they write an academic thesis. Formative feedback [4] can be one approach to guide students to new knowledge by reducing the uncertainty between performance and goals, keeping feedback as simple as possible and promoting a “learning” goal orientation via said feedback.

As academic writing involves a completely new way of working and writing for the student, the supervisor’s needs to provide sufficient support so that students can achieve what is expected. Nowadays when students get less classroom time and are expected to take increasing responsibility themselves for their learning [9] it becomes difficult to simultaneously have time to socialize students into the academic context. Students can no longer just follow the supervisor and grow into the role by observing and imitating [6]. The more practically oriented guide where students and supervisors work together with the different parts of the process has previously emerged among supervisors as important in working with bachelor’s thesis. But this requires more effort from the supervisor/s, which is poorly correlated with the increasing numbers of students and the decreasing time available for supervision time for each student [11,18]. Discussions between supervisors how to facilitate the students’ work without it taking too much time can be useful. Another aspect is to, during the course; give additional lectures in subjects which often take much of the time for supervision as academic writing and methodologically diverse ways of performing analysis.

One way of reducing time for supervision is to do it in groups. One of the challenges in group supervision is that the included students can be at different phases of the work process, which has been reported earlier [10]. This may be an inevitable and sometimes difficult factor for the supervisor to master. Seven of the par-
participants had had group supervision and were more or less positive towards this form of supervision. They described that they were in different phases, had been too focused on their own study and did not read the others’ writing or had time to provide feedback, the latter being one of the main positive features of group supervision. But they also described advantages of reading and discussing each other’s drafts. Receiving feedback from more than supervising lecturers have previously emerged as an advantage of group supervision but it is also known to increase scientific knowledge and make the students better prepared for examination [11,12]. In the current study the results indicate that the group supervision they had was more like individual supervision but given in a group [9]. However, the result may not be comparable to group supervision where all students take full participation.

The students were satisfied with individual supervision, although it had its pros and cons too. They were pleased that the focus was only on their own work, even if it was a week spot vulnerable to have only one supervisor. Many of the participants who received group supervision wanted additional or only individual supervision. They thought that there were benefits in getting more individual feedback and individual supervision would provide increased knowledge of the scientific method versus the unstructured group supervision they received. Supervision requires other skills than traditional teaching requires [2] and group supervision makes this even harder to provide. Though it is possible to combine different types of supervision. In a Norwegian study, multi voiced supervision of master’s thesis students were used. They mixed group and individual supervision with student colloquia and concluded that the different approaches complemented each other. The student colloquia filtered the first idea and texts, group supervision gave diverse feedback but also facilitated the students into the discipline and the individual supervision provided more specific advice.

An integrated Learning Environment (LE) to support undergraduate dissertations was developed and utilized in a business school in the UK [19]. The new approach included new uses of information technology to support work flow, observation of support, enhancement assessment regimes, improved communication and easy access to relevant documents. The implementation led to improvements to the student dissertation experience and achievement and seemed to also have enhanced the consistency and effectiveness of research supervisors. The results from this new approach are interesting as the participants in the current study pointed out several areas where they experienced uncertainty during the course. They felt that it was difficult to make contact with the supervisor and that the they were overlooked, as the supervisor did not have focus on their work or did not devote the time necessary to provide proper feedback. The participants described that they thought that the instructions they received was unclear and that supervisors’ personal opinions resulted inequality between students. These experiences could have been diminished with a more integrated learning environment. The lack of sufficient supervision has been highlighted in a previous study [14], in which the surveyed students felt they had received too little support and they did not know how they would proceed, resulting in an experience of uncertainty. However, no previous studies have had students describe that they have felt overlooked or had uninvolved supervisors. In this study, the supervisors were not interviewed. It would have been interesting to study how the supervisors describe the correspondent situations from their perspective and if they were aware of the uncertainty that students felt.

Twenty of 35 students were contacted and asked whether they wanted to participate in the study. Of those, 11 accepted and were interviewed. The stated reason for declining to participate in the study was a lack of time, as the interviews took place during the last two weeks of their very last semester. It would have been an advantage to perform the interviews at an earlier stage in the program, but this was not possible due to logistical reasons. It is impossible to know how these students, who chose not to participate in the study, experienced scientific supervision. As a result there may be experiences that we have been able to cover here. There is always a risk that the study participants are those students with a critical perception of supervision and the thesis course and vice versa. If you are content with your experiences of supervision, it is harder to prioritize an appointment for a follow-up. On the other hand, most interviewed students were pleased with their thesis course, although they felt there is potential for improvement in terms of both group and individual supervision [20, 21].

**Conclusion**

Physical therapy students’ experience of their supervision during their bachelor’s thesis course was dependent on the supervisors’ attributes, both favourable and unfavourable, difficulties with communication, being disregarded and affected by the supervisors’ personal views. This was also put in context of the current form of supervision as individual and group supervision brought both positive and negative factors to the experience of the process. Further research may investigate the supervisors’ experience of equal forms of supervision in the educational program to physiotherapists.
